

C Programming I

Alexander B. Pacheco LTS Research Computing June 3, 2015

Outline

- Introduction
- Program Structure
- Basic Syntax
- Data Types, Variables and Constants
- Programming Operators
- 6 Control Flow
- 2 Exercises

What is the C Language?

- A general-purpose, procedural, imperative computer programming language.
- Developed in 1972 by Dennis M. Ritchie at the Bell Telephone Laboratories to develop the UNIX operating system.
- The UNIX operating system, the C compiler, and essentially all UNIX applications programs have been written in C.
- C is the most widely used computer language.
 - Easy to learn
 - Structured language
 - Produces efficient programs
 - · Handles low-level activities
 - Can be compiled on a variety of computer plaforms
- Most of the state-of-the-art softwares have been implemented using C.
- Today's most popular Linux OS and RBDMS MySQL have been written in C.

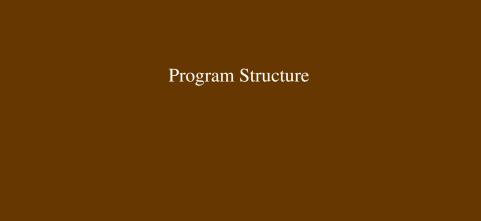

What do you need to learn C?

C Compiler

- What is a Compiler?
 - A compiler is a computer program (or set of programs) that transforms source code written in a programming language (the source language) into another computer language (the target language, often having a binary form known as object code).
- How does a compiler do?
 - Translate C source code into a binary executable
- List of Common Compilers:
 - GCC GNU Project (Free, available on most *NIX systems)
 - Intel Compiler
 - Portland Group (PGI) Compiler
 - Microsoft Visual Studio
 - IBM XL Compiler

Text Editor

- Emacs
- VI/VIM
- Notepad++ (avoid Notepad if you will eventually use a *NIX system)
- Integrated Development Environment: Eclipse, XCode, Visual Studio, etc

Program Structure

A C Program consists of the following parts

- Preprocessor Commands
- Functions
- Variables
- Statements & Expressions
- Comments

A Simple Hello World Code

```
#include <stdio.h>
int main ()
{
   /* My First C Code */
   printf("Hello World!\n");
   return 0;
}
```

Compile and execute the code

dyn100077:Exercise apacheco\$ gcc hello.c
dyn100077:Exercise apacheco\$./a.out
Hello World!

My First C Code

```
#include <stdio.h>
int main ()
{
   /* My First C Code */
   printf("Hello World!\n");
   return 0;
}
```

- #include <stdio.h> is a preprocessor command.

 It tells a C compiler to include stdio.h file before going to actual compilation.
- int main () is the main function where program execution begins.
- /* ... */ is a comment and ignored by the compiler.
- printf(...) is function that prints Hello World! to the screen.
- return 0; terminates main() function and returns the value 0.

Basic C Syntax I

- C is a case sensitive programming language i.e. program is not the same as Program or PROGRAM.
- Each individual statement must end with a semicolon.
- Whitespace i.e. tabs or spaces is insignificant except whitespace within a character string.
- All C statments are free format i.e. no specified layout or column assignment as in FORTRAN77.

```
#include <stdio.h>
int main () { /* My First C Code */ printf("Hello World!\n"); return 0;}
```

will produce the exact same result as the code on the previous slide.

 In C everything within /* and */ is a comment. Comments can span multiple lines.

```
/* this is single line comment */
/* This
is a
in ultiline comment */
```

Basic C Syntax II

- Always use proper comments in your code. Your code will most likely be handed to someone long after you are gone.
- Comments are completely ignored by compiler (test/debug code)

Valid Character Set in C language

| Alphabets | ABCDEFGHIJKLMNOPQRSTUVWXYZ |
|-----------|----------------------------|
| | abcdefghijklmnopqrstuvwxyz |
| Digits | 0123456789 |
| | |

| | Special Characters | | | | | | | | | | | | | |
|---|--------------------|---|---|---|---|---|---|----|---|---|---|---|---|---|
| , | _ | { | < | , | (| ^ | ; | \$ | / | * | + | [| # | ? |
| | & | } | > | " |) | ! | : | % | - | \ | - |] | ~ | |

| | Reserved | Keywords | |
|----------|----------|----------|----------|
| auto | double | int | struct |
| break | else | long | switch |
| case | enum | register | typedef |
| char | extern | return | union |
| continue | for | signed | void |
| do | if | static | while |
| default | goto | sizeof | volatile |
| const | float | short | unsigned |

• White space Characters: blank space, new line, horizontal tab, carriage return and form feed

Data Types, Variables and Constants

Data Types

Basic Types: There are five basic data types

- int integer: a whole number.
- ② float floating point value: ie a number with a fractional part.
- **1** double a double-precision floating point value.
- char a single character.
- o void valueless special purpose type.

Derived Types: These include

- Pointers
- Arrays
- Structures
- Union
- Function
- The array and structure types are referred to collectively as the aggregate types.
- The type of a function specifies the type of the function's return value.

Basic Data Types: Integer

| Type | Storage size (in bytes) | Value range |
|----------------|-------------------------|---------------------------------|
| char | 1 | -128 to 127 or 0 to 255 |
| unsigned char | 1 | 0 to 255 |
| signed char | 1 | -128 to 127 |
| | 2 | -32,768 to 32,767 |
| int | or | or |
| | 4 | -2,147,483,648 to 2,147,483,647 |
| | 2 | 0 to 65,535 |
| unsigned int | or | or |
| | 4 | 0 to 4,294,967,295 |
| short | 2 | -32,768 to 32,767 |
| unsigned short | 2 | 0 to 65,535 |
| long | 4 | -2,147,483,648 to 2,147,483,647 |
| unsigned long | 4 | 0 to 4,294,967,295 |

- To get the exact size of a type or a variable on a particular platform, you can use the size of operator.
- The expressions sizeof(type) yields the storage size of the object or type in bytes.

Basic Data Types: Floating-Point & void

| Type | Storage size | Value range | Precision (decimal places) |
|-------------|--------------|-----------------------|----------------------------|
| float | 4 bytes | 1.2E-38 to 3.4E38 | 6 |
| double | 8 bytes | 2.3E-308 to 1.7E308 | 15 |
| long double | 10 bytes | 3.4E-4932 to 1.1E4932 | 19 |

| Situation | Description |
|----------------------------|-----------------------------------|
| function returns as void | function with no return value |
| function arguments as void | function with no parameter |
| pointers to void | address of an object without type |

Variables

- Variables are memory location in computer's memory to store data.
- To indicate the memory location, each variable should be given a unique name called identifier.
- Variable names are just the symbolic representation of a memory location.
- Rules for variable names:
 - Ocomposed of letters (both uppercase and lowercase letters), digits and underscore '_' only.
 - 2 The first letter of a variable should be either a letter or an underscore.
 - There is no rule for the length of a variable name.
 - Most likely your code will be used by someone else, so variable names should be meaningful and short as possible.

```
int num;
float circle_area;
double _volume;
```

• In C programming, you have to declare variable before using it in the program.

Declaring Variable or Variable Definition

- A variable definition means to tell the compiler where and how much to create the storage for the variable.
- A variable definition specifies a data type and contains a list of one or more variables of that type as follows:

```
type variable_list;
```

- type must be a valid C data type or any user-defined object, etc., and variable_list may consist of one or more identifier names separated by commas.
- Variables can be initialized (assigned an initial value) in their declaration.

Constants & Literals

The constants refer to fixed values that the program may not alter during its execution. These fixed values are also called literals.

Integer Constants

```
85  /* decimal */
0213  /* octal */
0x4b  /* hexadecimal */
30  /* int */
30u  /* unsigned int */
301  /* long */
30ul  /* unsigned long */
```

Character Constants

```
'a' /* character 'a' */
'Z' /* character 'Z' */
\? /*? character */
\\ /*\ character */
\n /*Newline */
\r /*Carriage return */
\t /*Horizontal tab */
```

Floating Point Constants

```
3.1416

314159E-5 /* 3.14159 */

2.1E+5 /* 2.1x10<sup>5</sup>*/

3.7E-2 /* 0.037 */

0.5E7 /* 5.0x10<sup>6</sup>*/

-2.8E-2 /* -0.028 */
```

String Constants

```
"hello, world" /* normal string */
"c programming \ language" /* multi-line string */
```

How to define Constants

- Constants can be defined in two ways
 - ① Using the #define preprocessor (defining a macro)
 - ② Using the **const** keyword (new standard borrowed from C++)

```
#include <stdio.h>
/* define LENGTH using the macro */
#define LENGTH 5
int main()
{
   /*define WIDTH using const */
   const int WIDTH = 3;
   const char NEWLINE = '\n';
   int area = LENGTH * WIDTH;

   printf("value of area : %d", area);
   printf("%c", NEWLINE);
   return 0;
}
```

Input and Output

- C or any programming language in general needs to be interactive i.e. write something back and optionally read data to be useful.
- Similar to Unix, C treats all devices as files.

| Standard File | File Pointer | Device |
|-----------------|--------------|----------|
| Standard Input | stdin | Keyboard |
| Standard Output | stdout | Screen |
| Standard Error | stderr | Screen |

 C Programming language provides three functions to read/write from standard input/output

| | Unform | atted | Formatted |
|--------|---------|-------|-----------|
| Input | getchar | gets | scanf |
| Output | putchar | puts | printf |

Unformatted I/O

The getchar() & putchar() functions

- The int getchar (void) function reads the next available character from the screen and returns it as an integer.
 - This function reads only single character at a time.
- The int putchar (int c) function puts the passed character on the screen and returns the same character.
 - This function puts only single character at a time.

The gets() & puts() functions

- The char *gets(char *s) function reads a line from stdin into the buffer pointed to by s until either a terminating newline or EOF.
- The int puts (const char *s) function writes the string s and a trailing newline to stdout.

```
#include <stdio.h>
int main()
{
   int c;
   printf( "Enter a value :");
   c = getchar();
   printf( "\nYou entered: ");
   putchar( c );
   return 0;
}
```

```
#include <stdio.h>
int main()
{
    char str[100];
    printf( "Enter a value :");
    gets( str );
    printf( "\nYou entered: ");
    puts( str );
    return 0;
}
```

Formatted I/O

- The int scanf (const char *format, ...) function reads input from the standard input stream stdin and scans that input according to format provided.
- The int printf(const char *format, ...) function writes output to the standard output stream stdout and produces output according to a format provided (optional).

```
#include <stdio.h>
int main ()
{
    /* My Second C Code */
    char name[100];
    printf("Enter your name:");
    scanf("%s",&name);
    printf("Hello %s\n",name);
    return 0;
}
```

- In this program, the user is asked a input and value is stored in variable name.
- Note the '&' sign before name.
- Ename denotes the address of name and value is stored in that address.

Common Format Specifier

• The format specifier: %[flags][width][.precision][length]specifier

| flag | meaning |
|------|------------------------|
| - | left justify |
| + | always display sign |
| 0 | pad with leading zeros |

| Specifier | Output | Example |
|-----------|--|----------------|
| %f | decimal float | 3.456 |
| %7.5f | decimal float, 7 digit width and 5 digit precision | 3.45600 |
| %d | integer | 5 |
| %05d | integer, 5 digits pad with zeros | 00101 |
| %s | string of characters | "Hello World!" |
| %e | scientific notation for decimal float | 2.71828e+5 |
| %с | character | |
| \n | insert new line | |
| \t | insert tab | |

hello world

Programming Operators

Operators

Arithmetic

| Operator | Meaning |
|----------|--|
| + | addition or unary plus |
| - | subtraction or unary minus |
| * | multiplication |
| / | division |
| % | remainder after division(modulo division) |
| ++ | increase integer value by one |
| | decrease integer value by one |

• Assignment Operator

| Operator | Example | Same as |
|----------|---------|---------|
| = | a=b | a=b |
| += | a+=b | a=a+b |
| -= | a-=b | a=a-b |
| *= | a*=b | a=a*b |
| /= | a/=b | a=a/b |
| %= | a%=b | a=a%b |

Increment/Decrement Operator

- There are two types of increment/decrement operators
 - Suffix or Postfix: e.g. i++ or j-a=i++ means set a to i and then increment i by 1
 - Prefix: ++i or --j a=++i means increment i by 1 and then set a to i
- Consider the following example

```
If i = 1 and j = 2, then
++i + j++ = 4
```

and not 5 since j is incremented after the operation is complete

Relational Operators

- Relational operators checks relationship between two operands.
- If the relation is true, it returns value 1 and if the relation is false, it returns value 0.
- Relational operators are used in decision making and loops in C programming.

| Operator | Meaning | Example |
|----------|--------------------------|------------------------|
| == | Equal to | 5==3 returns false (0) |
| > | Greater than | 5>3 returns true (1) |
| < | Less than | 5<3 returns false (0) |
| != | Not equal to | 5!=3 returns true(1) |
| >= | Greater than or equal to | 5>=3 returns true (1) |
| <= | Less than or equal to | 5<=3 return false (0) |

Logical & Conditional Operators

- Logical operators are used to combine expressions containing relation operators.
- In C, there are 3 logical operators

| Operator | Meaning | Example |
|----------|-------------|---|
| && | Logial AND | If $c=5$ and $d=2$ then,(($c==5$) && ($d>5$)) returns false. |
| II | Logical OR | If $c=5$ and $d=2$ then, $((c==5) \parallel (d>5))$ returns true. |
| ! | Logical NOT | If $c=5$ then, $!(c==5)$ returns false. |

 Conditional Operator: Conditional operators are used in decision making in C programming, i.e, executes different statements according to test condition whether it is either true or false.

```
conditional_expression?expression1:expression2
```

 If the test condition is true, expression1 is returned and if false expression2 is returned.

```
d=(c>0)?10:-10;
```

If c is greater than 0, value of d will be 10 but, if c is less than 0, value of d will be -10.

Other Operators

• Bitwise Operators: works on bits and perform bit-by-bit operation

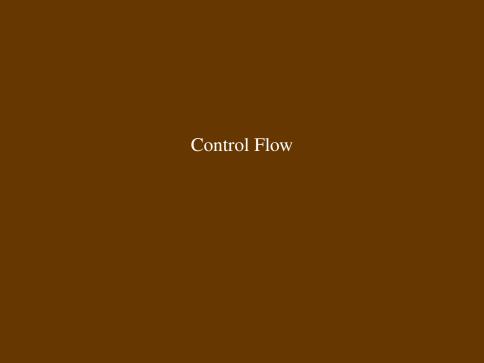

| Truth Table | | | | | |
|-------------|---|-------|------------|-------|--|
| p | q | p & q | $p \mid q$ | p ^ q | |
| 0 | 0 | 0 | 0 | 0 | |
| 0 | 1 | 0 | 1 | 1 | |
| 1 | 1 | 1 | 1 | 0 | |
| 1 | 0 | 0 | 1 | 1 | |

• Misc Operators

| Operator | Description |
|----------|-------------------------------------|
| sizeof() | Returns the size of an variable. |
| & | Returns the address of an variable. |
| * | Pointer to a variable. |
| ?: | Conditional Expression |

Operator Precedance

| Operator | Description | Associativity |
|------------|---|--------------------|
| | Suffix Increment/Decrement | Associativity → |
| ++, | | |
| ++, | Prefix Increment/Decrement | \leftarrow |
| +, - | Unary plus and minus | |
| !, ~ | Logical NOT and Bitwise NOT | |
| * | Indirection (dereference) | |
| & | Address of | |
| sizeof | Size-of | |
| *, /, % | Multiplication, division, modulo | \rightarrow |
| +, - | Addition, Subtraction | |
| «, » | Bitwise left and right shift | |
| <, <= | Relational Operators | |
| >,>= | | |
| ==, != | | |
| & | Bitwise AND | |
| ^ | Bitwise XOR | |
| 1 | Bitwise OR | |
| && | Logical AND | |
| II | Logical OR | |
| ?: | Ternary Conditional | \leftarrow |
| = | Simple Assignment | |
| +=, -= | Assignment by sum and difference | |
| *=, /=, %= | Assignment by product, quotient and remainder | |
| «=, »= | Assignment by bitwise left and right shift | |
| &=, ^=, l= | Assignment by logical AND, XOR and OR | |
| , | Comma Operator | \rightarrow |

Control Flow

- Conditional Statements (decision making/selection)
 - if · · · else if · · · else
 - switch
- Loops
 - for
 - while
 - do while

if statement

 An if statement consists of a boolean expression followed by one or more statements.

```
if(expression)
{
    /* statement(s) will execute if the boolean expression is true */
}
```

- If the boolean expression evaluates to true, then the block of code inside the if statement will be executed.
- If boolean expression evaluates to false, then the first set of code after the end of the if statement(after the closing curly brace) will be executed.

if · · · else statement

• An if statement can be followed by an optional else statement, which executes when the boolean expression is false.

```
if(expression)
{
    /* statement(s) will execute if the boolean expression is true */
}
else
{
    /* statement(s) will execute if the boolean expression is false */
}
```

• If the boolean expression evaluates to true, then the if block of code will be executed, otherwise else block of code will be executed.

if \cdots else if \cdots else statement

- An if statement can be followed by an optional else if $\cdot \cdot \cdot$ else statement,
- very useful to test various conditions using single if $\cdot \cdot \cdot$ else if statement.
- When using if, else if, else statements there are few points to keep in mind:
 - An if can have zero or one else's and it must come after any else if's.
 - An if can have zero to many else if's and they must come before the else.
 - Once an else if succeeds, none of the remaining else if's or else's will be tested.

```
if(expression 1)
{
    /* Executes when the boolean expression 1 is true */
}
else if( expression 2)
{
    /* Executes when the boolean expression 2 is true */
}
else if( expression 3)
{
    /* Executes when the boolean expression 3 is true */
}
else
{
    /* executes when the none of the above condition is true */
}
```

```
#include <stdio.h>
int main ()
  /* local variable definition */
  int a = 100;
  /* check the boolean condition */
  if(a < 20)
       /\star if condition is true then print the following \star/
       printf("a is less than 20\n" );
  else
       /* if condition is false then print the following */
       printf("a is not less than 20\n" );
  printf("value of a is : %d\n", a);
  return 0:
```

Nested if \cdots else statement

 You can use one if or else if statement inside another if or else if statement(s) i.e. nested if · · · else statement/s

```
if( expression 1)
{
    /* Executes when the boolean expression 1 is true */
    if( expression 2)
    {
        /* Executes when the boolean expression 2 is true */
    }
}
```

```
#include <stdio.h>
int main ()
  /* local variable definition */
  int a = 100;
  int b = 200;
  /* check the boolean condition */
  if(a == 100)
      /* if condition is true then check the following */
       if(b == 200)
          /* if condition is true then print the following */
         printf("Value of a is 100 and b is 200\n" );
  printf("Exact value of a is : %d\n", a );
  printf("Exact value of b is : %d\n", b );
  return 0;
```

switch statement I

- A switch statement allows a variable to be tested for equality against a list of values.
- Each value is called a case, and the variable being switched on is checked for each switch case.

```
switch(expression) {
    case constant-expression :
        statement(s);
        break; /* optional */
    case constant-expression :
        statement(s);
        break; /* optional */
    /* you can have any number of case statements */
    default : /* Optional */
        statement(s);
}
```

• The expression used in a switch statement must have an integral type (or enumerated type, or be of a class type in which the class has a single conversion function to an integral or enumerated type).

switch statement II

- You can have any number of case statements within a switch. Each case is followed by the value to be compared to and a colon.
- The constant-expression for a case must be the same data type as the variable in the switch, and it must be a constant or a literal.
- When the variable being switched on is equal to a case, the statements following that case will execute until a break statement is reached.
- When a break statement is reached, the switch terminates, and the flow of control jumps to the next line following the switch statement.
- Not every case needs to contain a break. If no break appears, the flow of control
 will fall through to subsequent cases until a break is reached.
- A switch statement can have an optional default case, which must appear at the end of the switch.
- The default case can be used for performing a task when none of the cases is true. No break is needed in the default case.

switch statement III

```
#include <stdio.h>
int main ()
   /* local variable definition */
   char grade;
   printf("Enter your grade:\n");
   scanf("%c", &grade);
   switch (grade)
   case 'A' :
      printf("Excellent!\n" );
     break:
   case 'B':
   case 'C' :
      printf("Well done\n" );
      break;
   case 'D' :
      printf("You passed\n" );
      break;
   case 'F' :
      printf("Better try again\n" );
      break;
   default :
```

switch statement IV

```
printf("Invalid grade\n" );
}
printf("Your grade is %c\n", grade );
return 0;
```

Nested Conditional Statements

• Conditional statements can be nested as they do not overlap:

```
if( expression 1) {
  if(expression 2) {
    /* Executes when the boolean expression 2 is true */
    /* nested switch statement */
    switch (expression) {
    case constant-expression :
      statement(s);
     break; /* optional */
    case constant-expression :
      statement(s);
     break; /* optional */
      /* you can have any number of case statements */
    default : /* Optional */
      statement(s):
```

for loop

- A for loop is a repetition control structure that allows you to efficiently write a loop that needs to execute a specific number of times.
 - The init step is executed first and only once.
 - the condition is evaluated. If it is true, the body of the loop is executed. If it is false, the body of the loop does not execute, the loop exits.
 - the increment statement executes after the loop body.
 - The loop continues until the condition becomes false

```
for ( init; condition; increment )
{
    statement(s);
}
```

while and do··· while loops

- while loops are similar to for loops
- A while loop continues executing the code block as long as the condition in the while holds.

```
while(condition)
{
    statement(s);
}
```

• do··· while loop is guaranteed to execute at least one time.

```
do
{
   statement(s);
}while(condition);
```

Simple loops using for, while, do while

```
#include <stdio.h>
int main ()
 int i:
 /* for loop execution */
 for (i = 0; i < 5; i++) {
   printf("for loop i= %d\n", i);
 i=0:
 /* while loop execution */
 while (i < 5)
   printf("while loop i: %d\n", i);
   i+=1;
 i=1:
 /* do-while loop execution */
 do {
    printf("do while loop i: %d\n", i);
   i=i+1;
  \}while(i < 0);
 return 0;
```

Nested loops in C

• All loops can be nested as long as they do not overlap

```
/* nested for loops*/
for (init; condition; increment) {
   for (init; condition; increment) {
      statement(s);
   }
   statement(s);
}

* nested while loops*/
while (condition) {
   while (condition) {
      statement(s);
   }
   statement(s);
}
```

```
/* nested do while loops*/
do {
    statement(s);
    do {
        statement(s);
    } while ( condition );
} while ( condition );
/* mixed type loops*/
while (condition) {
    for (init; condition; increment) {
        statement(s);
        do {
            statement(s);
        } while ( condition );
}
statement(s);
```

```
#include <stdio.h>
int main () {
   int i, j, k, n=2;
   printf("i j k\n");
   /* Nested for loops */
   for (i=0; i<n; ++i)
        for (j=0; j<n; j++)
        for (k=0; k<n; ++k)
   printf("%d %d %d\n", i,j,k);
   return 0;
}</pre>
```

Loop Control Statement

• Loop control statements change execution from its normal sequence.

break: Terminates the loop or switch statement

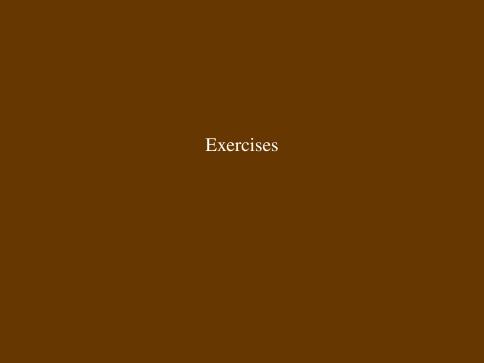

continue: Causes the loop to skip the remainder of its body for the current

iteration

goto: Transfers control to the labeled statement. Use is not advised

```
#include <stdio.h>
int main ()
{
    /* local variable definition */
    int a = 10;

    /* while loop execution */
    while (a < 20)
    {
        printf("value of a: %d\n", a);
        a++;
        if(a > 15)
    {
            /* terminate the loop using break statement */
            break;
        }
        }
    return 0;
```

Exercise

- Print list of prime numbers less than 100
- Calculate circumference and area of a circle for given radius
- Calculate factorial of a number
- Calculate the Greatest Common Divisor and Least Common Multiple between two integers

List of Prime Numbers

Algorithm 1 Pseudo code to get list of prime numbers

```
\begin{array}{l} \textbf{program} \ \mathsf{PRIMENUMBERS} \\ \textbf{for} \ 2 \leq i \leq 100 \ \textbf{do} \\ \textbf{for} \ 2 \leq j \leq (i/j) \ \textbf{do} \\ \textbf{if} \ (i\%j \neq 0) \ \texttt{i} \ \ \texttt{is} \ \ \texttt{prime} \\ \textbf{end for} \\ \textbf{end for} \\ \textbf{end program} \ \mathsf{PRIMENUMBERS} \end{array}
```

Calculate Area and Circumference

 Write a code to read a radius from standard input and calculate area and circumference of a circle of that radious

Algorithm 2 Pseudo code for calculating area and circumference

program AREACIRCUM

Define π

 $r \leftarrow \text{some number}$

 $a=\pi r^2$

 $c = 2\pi r$

end program AREACIRCUM

Factorial

• Calculate factorial and double factorial of a number

Algorithm 3 Pseudo Code for Factorial

```
\begin{aligned} & \textbf{program} \; \text{FACTORIAL} \\ & n \leftarrow \text{a number} \\ & \textbf{do} \; i \leftarrow n, n-1, n-2 \cdots 1 \\ & f = f * i \\ & \textbf{end do} \\ & \textbf{end program} \; \text{FACTORIAL} \end{aligned}
```

Calculate GCD & LCM I

- In mathematics, the greatest common divisor (gcd) of two or more integers, when at least one of them is not zero, is the largest positive integer that divides the numbers without a remainder.
- Using Euclid's algorithm

$$gcd(a, 0) = a$$

 $gcd(a, b) = gcd(b, a\%b)$

• In arithmetic and number theory, the least common multiple of two integers a and b is the smallest positive integer that is divisible by both a and b.

$$lcm(a,b) = \frac{\mid a \cdot b \mid}{gcd(a,b)}$$

Calculate GCD & LCM II

Algorithm 4 Pseudo Code to calculate gcd

```
program GCDLCM a,b \leftarrow \text{two integers} do while b \neq 0 t \leftarrow v, v \leftarrow u\%v, u \leftarrow t end do gcd \leftarrow |u| lcm \leftarrow |a \cdot b|/gcd end program GCDLCM
```
